For forming a ferroelectric film consisting of lead zirconate titanate using the sol gel method, a method to form a ferroelectric film containing respectively:

a process (a) for obtaining fatty acid lead [compound];

a process (b) for obtaining titanium•alkoxide;

a process (c) for obtaining zirconium•alkoxide having the same alcohol residues as the said titanium•alkoxide;

and a process (d) for forming lead titanium•double alkoxide and lead zirconium•double alkoxide by mixing the aforementioned fatty acid lead, the aforementioned titanium•alkoxide, and the aforementioned zirconium•alkoxide.

Results

Hydrolysis and the condensation reaction of each of the double alkoxides advance uniformly, the thin PZT film formed has sufficient electrical characteristics such as the display of a smooth surface, a large remanence, and a small leakage of current, for example, and satisfies the demanded performance.

EP 0 674 019 A1

Industrial application field

This invention is concerned with a method for forming a ferroelectric film (in particular, a lead zirconate titanate (PZT) film) by the sol gel method, a method to manufacture a capacitor (in particular, a capacitor in a semiconductor memory cell), a method to prepare its source solution, and the source solution.

Conventional technology

An ONO film that is structured to have successively laminated SiO_2 , Si_3N_4 , and SiO_2 is used as an insulating film (dielectric film) that makes up a capacitor for memory cells in a dynamic RAM, for example.

However, the effective dielectric constant of said ONO film is small, at approximately 5, so the thickness of the capacitor dielectric film must be made thin under restrictions that concern the size of the area and complexity of shape that is required in order to expand the area when a large-capacity memory of less than 256 Mb is used, thus bringing much difficulty into the process.

Contrary to this, a perovskite crystal structure type of ferroelectric material containing a relatively large dielectric constant, from several 100 to several 1000, has been recognized as a future insulating material for capacitors in the dynamic RAM.

For forming a PZT film, referred to as $\text{Pb}(\text{Zr}, \text{Ti})\text{O}_3$, among the ferroelectric materials, the sol gel method, CVD (chemical vapor-phase growth) method, and the sputtering method, for example, can be used as the method for forming thin films. Formation by the sol gel method is particularly preferable. When forming films by the sol gel method, the quality of the source solution (sol gel solution) prepared determines the electrical characteristics of the thin film obtained at the end.

The method for preparing the source solution (sol gel solution) used in the formation of the $\text{Pb}(\text{Zr}, \text{Ti})\text{O}_3$ thin film by the sol gel method will be explained in Figure 18.

First, the hydrate lead triacetate $\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$ as the raw material is diluted with a solvent (methoxyethanol is often used in many cases, for example) in process 1.

The water of crystallization of the hydrate lead triacetate is successively eliminated through boiling at 120-160 °C in process 2.

Next, titanium isopropoxide $\text{Ti}\{(\text{CH}_3)_2\text{CHO}\}_4$ and zirconium n-butoxide $\text{Zr}\{(\text{CH}_3(\text{CH}_2)_2\text{CH}_2\text{O})_4$ are added to said lead acetate solution in process 3. Diethanolamine may be added at the same time as a stabilizer.

The mixing concentration of each of the aforementioned elements is also indicated in Figure 18. The amount of methoxyethanol used as the solvent is adjusted in the preparatory stage of the source solution, so it is not indicated.

Next, a double alkoxide of titanium-lead and zirconium-lead is formed through distillation at 120-160 °C in process 4. This double alkoxide is presumed to be formed in accordance with the reaction formula indicated below.

The concentration is successively adjusted in process 5 by supplementing for the solvent that was evaporated in process 4.

Furthermore, through adding water in process 6 and stirring in process 7, the double alkoxide formed in process 4 is allowed to undergo hydrolysis and a condensation reaction, then the aforementioned polymerization of the metallic oxides is promoted to prepare the sol gel solution. This process is presumed to advance in accordance with the reaction formula indicated below.

Hydrolysis (partial hydrolysis is assumed):

Condensation reaction (however, M represents Ti or Zr, and R is $-\text{CH}(\text{CH}_3)_2$ or $-\text{CH}_2(\text{CH}_2)_2\text{CH}_3$):

10 In this case, the actual polymerization occurs through the repeated advancing of hydrolysis and condensation of the double alkoxide in the following manner (however, R represents $-\text{CH}(\text{CH}_3)_2$ or $-\text{CH}_2-(\text{CH}_2)_2\text{CH}_3$).

40 The characteristic of the PZT sol gel solution obtained in this manner is that the metallic oxides are polymerized through the hydrolysis and condensation in process 6 and process 7.

This sol gel solution (source solution) is then coated on top of a substrate by the spin-coating method or the dip-coating method, for example, dried at a temperature of 100-300°C, with the thin-coated sol gel film being changed into a dried gel condition (polymer gel).

45 Next, a thin sintered film of $\text{Pb}(\text{Zr}, \text{Ti})\text{O}_3$ with a perovskite crystal structure -- the thin PZT film -- is formed from the dry gel through an oxidation sintering process in a high-temperature oxidizing atmosphere of above 600°C.

However, it was confirmed that membrane formation is uneven when said thin PZT film is used as a dielectric film in a capacitor, for example, in a memory cell, and the electrical resistance is small.

50 Through diligent examination for the objective of the invention, this inventor has discovered that the addition of titanium-isopropoxide and zirconium-n-butoxide to the lead acetate solution (methoxyethanol, for example, as the solvent) in the aforementioned process 3, and block distillation of these in the aforementioned process 4 for forming a double alkoxide, extends an adverse influence onto the polymerization of the alkoxide in processes 6 and 7 that follow.

55 More precisely, each of the double alkoxides: $\text{PbTiO}_2\{\text{OCH}(\text{CH}_3)_2\}_2$ and $\text{PbZrO}_2\{\text{OCH}_2(\text{CH}_2)_2\text{CH}_3\}_2$ formed in process 4 has different alcohol residues (OR), so the hydrolysis and condensation in process 6 and process 7 do not uniformly advance, and different types of alcohol residues (OR) are mixed and present in the molecules formed in each of these reaction stages.

Such different alcohol residues, namely the isopropoxy group and the n-butoxy group, have a different reaction speed during hydrolysis and may react with other by-products in some cases. Therefore, it is highly possible that various types of molecular structures will be mixed and present in the condensation products formed, that structural separations will be caused, or various types of by-products will be formed.

Moreover, methoxyethanol used as the solvent also participates in the reaction in the manner below, so this solvent reacts with the alkoxide of process 3 during process 4 and mixes with the double alkoxide, further allowing the reaction to be nonuniform. This cannot be avoided even when the aforementioned alcohol residues (OR) are the same in both double alkoxides.

As described above, with respect to the existing sol gel solution, reactions of the double alkoxide during the manufacturing process, and the polymerization reaction through hydrolysis and condensation afterwards, occur nonuniformly. Therefore, membranaceousness and electrical characteristics such as remanence, for example, of the thin PZT film formed, are easily insufficient and do not satisfy the performance demanded.

Problems to be solved by the invention

The aim of this invention is to provide: a method for forming a ferroelectric film having excellent membranaceousness and electrical characteristics as a result of uniform reactions during the preparatory processes for the sol gel solution, along with a satisfactory acceleration in the polymerization of the metallic oxides. It also concerns a method for manufacturing a capacitor using said film, as well as a method for preparing the source solution (sol gel solution), and the source solution itself.

Means for solving the problems

This inventor has elucidated the complicated reactions occurring during the aforementioned preparatory processes for the sol gel solution, has clarified the polymerization processes of a precursor of the metallic oxide (double alkoxide) by reviewing the processing conditions of the preparatory processes, and has established new preparatory processes.

More precisely, in forming a ferroelectric film consisting of lead zirconate titanate by the sol gel method, this invention involves a process consisting of:

- a process (a) for obtaining fatty acid lead,
- a process (b) for obtaining titanium•alkoxide,
- a process (c) for obtaining zirconium•alkoxide that has the same alcohol residue as said titanium•alkoxide,

and a process (d) for forming lead titanium•double alkoxide and lead zirconium•double alkoxide by mixing together the aforementioned fatty acid lead, the aforementioned titanium•alkoxide, and the aforementioned zirconium•alkoxide.

It is recommended that the method for forming the ferroelectric film in this invention consists of:

a process (a) for forming fatty acid lead (lead acetate $\text{Pb}(\text{CH}_3\text{COO})_2$, for example) in which a hydrate fatty acid lead (hydrate lead acetate $\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$, for example) is first diluted by an alcohol solvent (methoxyethanol $\text{CH}_3\text{OC}_2\text{H}_4\text{OH}$, for example) then boiled at 120-180 °C, for example, for 30 min to 2 h in order to eliminate the water of crystallization,

a process (b) for forming titanium•alkoxide (titanium•methoxyethoxide $\text{Ti}(\text{OC}_2\text{H}_4\text{OCH}_3)_4$, for example) through an alcohol exchange in which titanium•alkoxide (titanium•isopropoxide $\text{Ti}\{(\text{CH}_3)_2\text{CHO}\}_4$, for example) as the raw material is first diluted by the aforementioned alcohol solvent, then boiled at a temperature above the boiling point of the alcohol (isopropyl alcohol $(\text{CH}_3)_2\text{CHOH}$, for example), which is an element of said titanium•alkoxide, (70-190 °C, for example) for 30 min to 2 h, for example,

a process (c) for forming zirconium•alkoxide (zirconium•methoxyethoxide $\text{Zr}(\text{OC}_2\text{H}_4\text{OCH}_3)_4$, for example) through an alcohol exchange in which zirconium•alkoxide (zirconium•n-butoxide $\text{Zr}\{\text{CH}_3(\text{CH}_2)_2\text{CH}_2\text{O}\}_4$, for example) as the raw material is first diluted by the aforementioned alcohol solvent, then boiled at a temperature above the boiling point of the alcohol (n-butyl alcohol $\text{CH}_3(\text{CH}_2)_2\text{CH}_2\text{OH}$, for example), which is an element of said zirconium•alkoxide, (70-190 °C, for example) for 30 min to 2 h, for example,

and a process (d) for forming titanium lead•double alkoxide (titanium lead•dimethoxyethoxide $\text{PbTiO}_2\text{-(OC}_2\text{H}_4\text{OCH}_3)_2$, for example) and zirconium lead•double alkoxide (zirconium lead•dimethoxyethoxide $\text{PbZrO}_2\text{(OC}_2\text{H}_4\text{OCH}_3)_2$, for example) in which the aforementioned fatty acid lead, the aforementioned titanium•alkoxide formed through the aforementioned alcohol exchange, and the aforementioned zirconium•alkoxide are boiled at a temperature (120-200 °C, for example) above the boiling points of the alcohol in the aforementioned alcohol solvent and the fatty acid ester (methoxyethyl acetate, for example), as the elements of the aforementioned fatty acid lead, for 3-10 h, for example.

After forming said titanium lead•double alkoxide and zirconium lead•double alkoxide, ideally these reaction products are cooled to room temperature, the concentration is adjusted with the addition of the aforementioned alcohol, and hydrolysis and a condensation reaction are further provided for the aforementioned reaction products through the addition of water and stirring (stirring for 12-36 h above the boiling point of water, for example) in order to polymerize the aforementioned reaction products.

Precipitation of the products and formation of the by-products can be prevented by boiling the reaction solution at a temperature above 100 °C after the polymerization of said reaction products.

A stabilizer consisting of an alkanolamine (diethanolamine, for example) and/or β -diketone (acetylacetone, for example) may be added in order to prevent the precipitation of the products at least during the process for forming the titanium lead•double alkoxide and zirconium lead•double alkoxide from each of the aforementioned processes. The amount added is preferably less than 1.0 times that of the total number of moles of the constitutive metals of the ferroelectric film.

Quaternary metallic elements such as lanthanum, niobium, and iron, for example, may be added during the forming process of the double alkoxide, for example, in the aforementioned processes in order to prevent fatigue (reduction in the remanence value) and a leakage of current through an inversion of the voltage applied when the formed thin PZT film is used.

After preparing the source solution (sol gel solution) through the aforementioned polymerization of the reaction products using the method in this invention, a ferroelectric film can be formed by coating this source, forming a dry film by drying this coated source solution, and sintering said dry film.

This invention also provides a method for manufacturing a capacitor (capacitor in a semiconductor memory device, for example) in which the ferroelectric film is formed by coating the aforementioned prepared source solution on top of an upper electrode, drying it, and sintering the obtained dry film, with the unnecessary portion of this film being eliminated and the ferroelectric film being left in a specific pattern on top of the aforementioned upper electrode, and with an upper electrode being further formed on top of said ferroelectric film.

This invention also provides a method to prepare a source solution for the ferroelectric film through each of the aforementioned processes, and also provides the prepared source solution itself.

Brief explanation of the figures

15 Application example

This invention will be explained in an application example below.

First, the method to prepare the source solution (sol gel solution) used for forming the thin PZT film indicated in a specific example will be explained according to Figure 1.

20 The main processes in the preparatory method for this source solution consist of: process I in which water of crystallization in the hydrate lead triacetate $\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$ is eliminated; processes II and III in which titanium·isopropoxide $\text{Ti}\{(\text{CH}_3)_2\text{CHO}\}_4$ and zirconium·n-butoxide $\text{Zr}\{\text{CH}_3(\text{CH}_2)_2\text{CH}_2\text{O}\}_4$ are respectively provided with an alcohol exchange after being diluted with a solvent (methoxyethanol $\text{CH}_3\text{OC}_2\text{H}_4\text{OH}$); process IV in which a double alkoxide is formed and the by-products are eliminated at the
25 same time; and processes VII and VIII in which polymerization through hydrolysis and the condensation reaction are accelerated. Each of the processes will be successively explained below.

Process I (Elimination of the water of crystallization)

30 The abbreviations of $[\text{CH}_3\text{CO}-] = \text{Ac}$ (acetyl group) and $[\text{CH}_3\text{OC}_2\text{H}_4-] = \text{Rm}$ (methoxyethyl group) will be used with the intention to simplify the chemical formulas. The water of crystallization in the hydrate lead triacetate $\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$ is eliminated in this process through heating above the boiling point of water, particularly at 120-180 °C (160 °C, for example) for 30 min to 2 h (1 h, for example).

The following esterification takes place between the Ac groups and the Rm groups in succession to this elimination of the water of crystallization, and $\text{Pb}(\text{ORm})_2$ (lead·methoxyethoxide) and RmOAc (methoxyethyl acetate) being formed.

In this case, the amount of RmOAc formed is approximately 6% of the total Ac number of moles, indicating the effective co-existence of $\text{Pb}(\text{OAc})_2$ and $\text{Pb}(\text{ORm})_2$ in the solution in process I.

45 Process II (preparation of the Ti solution)

50 An abbreviation of $[(\text{CH}_3)_2\text{CH}-] = \text{Rp}$ (isopropyl group) is used here. The solvent $\text{CH}_3\text{OC}_2\text{H}_4\text{OH}$ has a $[-\text{OH}]$ (hydroxyl group) and performs an alcohol exchange between $\text{Ti}(\text{ORp})_4$ through boiling above the boiling point (82.5 °C) of isopropyl alcohol RpOH , particularly 70-190 °C (160 °C, for example), for 30 min to 2 h (1 h, for example).

55 This equation (3) is an equilibrium reaction, therefore, the value of x differs according to each of the initial concentrations, and $\text{Ti}(\text{ORm})_4$ can be obtained when $x = 4$.

Process III (preparation of the Zr solution)

An abbreviation of $[\text{CH}_3(\text{CH}_2)_2\text{CH}_2-] = \text{R}_b$ (n-butyl group) is used here. The solution $\text{CH}_3\text{OC}_2\text{H}_4\text{OH}$ has a $[-\text{OH}]$ (hydroxyl group) and performs an alcohol exchange between $\text{Zr}(\text{OR}_b)_4$ through boiling above the boiling point (117.4°C) of n-butanol R_bOH , particularly $70-190^\circ\text{C}$ (160°C , for example), for 30 min to 2 h (1 h, for example).

This equation (4) is an equilibrium reaction, so the value of x differs according to each of the initial concentrations, and $\text{Zr}(\text{ORm})_4$ can be obtained when $x = 4$.

Process IV (mixing of the solutions, preparation of double alkoxide, and elimination of the by-products)

The solutions prepared in processes I, II, and III are mixed and the solvents R_pOH , R_bOH , and RmOAc are eliminated through heating and stirring (distillation) above the boiling point (143°C) of methoxyethyl RmOAc , particularly $120-200^\circ\text{C}$ (180°C , for example) for 3-10 h (6 h, for example). An elementary reaction formula for each solution is rearranged below.

The concentration of the solution (methoxyethanol RmOH as the solvent: boiling point 124°C) at each of said processes is as listed below.

0.01-2.0 mol/L as $\text{Pb}(\text{OAc})_2$: $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$, 0.275 mol/L, for example (The Pb concentration is excessive)

$\text{Ti}(\text{OR}_p)_4$: 0.05-1.0 mol/L, 0.125 mol/L, for example

$\text{Zr}(\text{OR}_b)_4$: 0.05 ~ 1.0 mol/L, 0.125 mol/L, for example

The boiling points of the by-products here are as listed below.

R_pOH (isopropyl alcohol) :bp = 82.5°C

R_bOH (n-butanol) :bp = 117.4°C

RmOAc (methoxyethyl acetate) :bp = 143.0°C

As described above, the aforementioned elementary reactions (2) to (4) advance towards the right by eliminating R_pOH , R_bOH , and RmOAc through distillation at 180°C , for example. However, as described above, RmOAc during distillation is stabilized at approximately 6% of the total Ac number of moles. Therefore, most of the Pb during process I is $\text{Pb}(\text{OAc})_2$, and a small amount of $\text{Pb}(\text{ORm})_2$ coexists. The reactions continuously progress towards the right during processes II and III, and $\text{Ti}(\text{ORm})_4$ and $\text{Zr}(\text{ORm})_4$ are mainly formed.

The aforementioned reaction products react in the following manner in process IV, and double alkoxide $\text{PbTiO}_2(\text{ORm})_2$ and $\text{PbZrO}_2(\text{ORm})_2$ are formed.

The double alkoxide obtained in this manner consists of the structural formula below.

Key: 1 (M represents Ti or Zr)

The material remaining during this reaction after a distillation at 180 °C, for example, consists mainly of the double alkoxide $\text{PbMO}_2(\text{OR}_m)_2$; a small amount of $\text{Pb}(\text{OR}_m)_2$ and RmOH is also present.

Process V (cooling)

The high-temperature double alkoxide solution obtained in process IV is first cooled to room temperature, and is shifted to process VI which follows.

Process VI (adjustment of the concentration)

The concentration of the double alkoxide increases according to the consumption or distillation of RmOH during the aforementioned process, so the solvent RmOH is added to dilute it to the desirable concentration.

Process VII (addition of water = hydrolysis)

Water at a number of moles that is the same as the total number of moles of metal of the solution is added to the double alkoxide solution with an adjusted concentration to perform hydrolysis (however, RmOH may be further added).

More precisely, the aforementioned organometallic compound (double alkoxide) is formed as an intermediate product in the solution obtained through distillation during process IV, and the $-\text{OR}_m$ groups that are present in such material undergo hydrolysis when encountering H_2O , as indicated below, and are changed into $[-\text{OH}]$ groups.

Furthermore, $-\text{OH}$ condenses with other $-\text{OH}$, and the H_2O formed here again contributes to hydrolysis.

Process VIII (stirring and polymerization of double alkoxide)

$[-\text{OR}_m]$ is transformed into $[-\text{OH}]$ in the aforementioned reaction and polymerization further advances through condensation. This can be sufficiently attained through stirring, particularly above the boiling point of water (120 °C, for example), for 12-36 h (24 h, for example) according to the reaction indicated below (M represents Ti or Zr).

The double alkoxide is polymerized as these reactions (7) and (8) successively advance. In this manner, a polymerized solution for the double alkoxide (metallic oxide) intended, which is a sol gel solution used to form the thin PZT film, can be obtained.

Next, polymerization of the aforementioned $\text{Pb}(\text{ORm})_2$ (methoxyethoxide lead) that is formed as an intermediate product will be considered. First, $[-\text{ORm}]$ is transformed into $[-\text{OH}]$ as in the equation below through the aforementioned hydrolysis, condensation of $[-\text{OH}]$ occurs in succession, and $[-\text{Pb-O-}]$ is polymerized through repeating these reactions.

As can be clearly observed in the explanation above, the preparatory method for the sol gel solution based on this invention is characterized by having the alcohol residue (ORm) for each of the reaction products titanium-alkoxide $\text{Ti}(\text{ORm})_4$ and zirconium-alkoxide $\text{Zr}(\text{ORm})_4$, particularly during the forming process (process IV) of the double alkoxide, already matched in processes II and III. That characteristic allows for a prominent interaction that could not be expected in the existing methods.

More precisely, hydrolysis and condensation advance uniformly (without a substantial difference in each of the double alkoxides) in processes VII and VIII because the alcohol residue (ORm) for each of the aforementioned double alkoxides formed in process IV is the same. Accordingly, the alcohol residue in the high-molecular-weight compound of metallic oxides obtained becomes uniform, the molecular structure becomes constant (without structural separation), and the types of by-products (RmOAc) are reduced for easy elimination.

Moreover, the same methoxyethanol (RmOH) is used as the solvent in all of the aforementioned processes I, II, and III, so the formation reaction and polymerization reaction of the aforementioned metallic

alkoxide and double alkoxide advance uniformly through the participation of this solvent in the reaction, and the types of by-products (RmOAc, for example) are reduced for easy elimination.

With respect to the by-products, the processing temperature in processes II, III, and IV is established at above the boiling point of the by-products that are to be eliminated (H_2O , RmOAc, R_pOH , and R_pOH), so undesirable by-products can be sufficiently eliminated and the polymerization reaction of the metallic oxide that follows can be more uniformly attained.

Accordingly, a uniform formation reaction of the double alkoxide and a polymerization reaction through hydrolysis and condensation afterwards can be attained and by-products can be sufficiently eliminated with the sol gel solution prepared based on this invention. Therefore, intermolecular stress caused by the structural separation and decomposition of the organic groups can be lessened and defects in density such as pores, for example, can be reduced, and the thin PZT film formed has sufficient electrical characteristics such as the display of a smooth surface, a large remanence, and a small leakage of current, for example, thus satisfying the demands on performance.

Precipitation from the solution can be prevented by boiling the solution at a temperature higher than $100^\circ C$ after completion of the aforementioned process VIII.

Quaternary metallic elements such as lanthanum, niobium, and iron, for example, may be added during the forming process of the double alkoxide, for example, among the aforementioned processes in order to prevent fatigue (reduction in the remanence value) and a leakage of current through an inversion of the voltage applied when the thin PZT film is being used.

Precipitation of the reaction products in the solution can be prevented by adding an alkanolamine (diethanolamine, for example) and/or β -diketone (acetylacetone, for example) as a stabilizer. It is possible to advance the reaction by adding an appropriate amount of this stabilizer at least in process IV (however, such an addition in processes II and III is not recommended if circumstances allow) among the aforementioned process II, process III, process IV, and process VIII. The amount added is recommended to be less than 1.0 times that of the total number of moles of metal of the constitutive elements of the ferroelectric film when the intention is to improve the performance of the thin PZT film (improvement of the remanence density, for example).

Diethanolamine $NH(C_2H_4OH)_2$, for example, that is mixed as the stabilizer has the function of preventing the precipitation of $M(OH)_n$ through the binding and formation of $\{NH(C_2H_4O)_2\}_nM$, and the polymerization of the metallic atoms that are bound with $NH(C_2H_4OH)_2$ does not advance further.

More precisely, the chemical equilibrium of Pb, which constitutes higher oxide polymers after condensation, and H_2O remaining in the solution is indicated in the reaction formula of equation (11) below. $Pb(OH)_2$ is formed through this reaction, $NH(C_2H_4O)_2 Pb$ is further formed in the reaction indicated in equation (12), and the condensation of $[-Pb-O-]$ stops. This reaction product is released from the inside of the film through a tentative sintering during the formation of the thin PZT film which will be described later, so less problems occur. A similar reaction does not only occur with Pb, but can also be considered for Ti and Zr; it is thought that the reaction of Pb with a weak binding preferentially advances. Accordingly, $NH(C_2H_4OH)_2$ has the function of preventing precipitation by controlling hydrolysis, and has the function of controlling the polymerization of $[-Pb-O-]$.

A stabilizer such as diethanolamine, for example, can be added to a concentration of 0.25 mol/L, for

example, but such an addition is not required when the aforementioned reaction ideally advances, and is in a condition in which precipitation does not occur (not forming $M(OH)_n$). However, diethanolamine at approximately 10% of the total number of moles of metal can be added after stirring in the aforementioned process VIII in order to prevent precipitation when formation is expected after a period of time due to moisture in the air.

H_2O is eliminated and the progress of the aforementioned reaction (11) is prevented, which stops $M(OH)_n$ from being formed, when stirring in the aforementioned process VIII is performed above the boiling point of water, at approximately $120^\circ C$, for example.

Next, the method for forming the thin PZT film using the PZT sol gel solution prepared in the aforementioned processes will be described in Figure 2.

First, the sol gel solution obtained in the aforementioned preparatory processes (Figure 1) is coated over a Si substrate by the spin coat method (or the dip coat method) in process IX. A Pt film (thickness of 2000 \AA) and a Ti film (thickness of 500 \AA) in this order from the top, as a lower electrode, are formed on top of a SiO_2 film (thickness of 1000 \AA) over the Si substrate by the sputtering method or the CVD method, with the aforementioned sol gel solution being coated upon the uppermost Pt film. The coating thickness when dried may be 2000 \AA .

The substrate, onto which the sol gel solution is coated, is successively dried for 3 min, for example, over a heating block warmed to $100-300^\circ C$ ($170^\circ C$, for example) in process X, and a tentative sintering is provided for 10 min, for example, at above $600^\circ C$ ($650^\circ C$, for example) in process XI. After repeating process IX to process XI for an intended number of times, a permanent sintering is provided for 1 h, for example, at above $600^\circ C$ ($650^\circ C$, for example) in process XII.

A thin PZT film with a thickness of 2000 \AA was obtained through said procedure. An Au upper electrode was formed by the sputtering method at the surface of the thin PZT film obtained; the electrical characteristics measured are indicated in Figures 3-5.

Figure 3 indicates C-V curves that are measured by the Quasistatic method (quasistatic C-V measuring method: $dV/dt = 0.2 \text{ V/sec}$). The measurement voltage is established between $\pm 1.65 \text{ V}$ and $\pm 4.0 \text{ V}$. The capacitance of the thin PZT film formed by the solution based on this invention increases together with the measurement voltage as indicated by the solid lines, displaying characteristic peculiar to the ferroelectric film.

Contrary to this, the capacitance of the thin PZT film formed with the existing solution (refer to Figure 18) is small as indicated by the broken lines, even when the measurement voltage is $\pm 4.0 \text{ V}$.

Figure 4 indicates hysteresis curves that are determined by the C-V curves in Figure 3. The remanence value P_r of the thin PZT film based on this invention increases in proportion to the increase in the measurement voltage as indicated by the solid lines, and a value of $19.0-20.0 \text{ } \mu\text{C/cm}^2$ was obtained during a measurement at $\pm 4 \text{ V}$. This remanence density is at the level that allows for the storage of a large amount of electrical charge of $380-400 \text{ fC}/\mu\text{m}^2$ when a capacitor in a nonvolatile memory, which will be described later, is prepared using the thin PZT film. This level far exceeds the $100 \text{ fC}/\mu\text{m}^2$ that is required. The resistance electrical field E_c is small and switching is easy.

Contrary to this, a remanence density of approximately only $10 \text{ } \mu\text{C/cm}^2$ was obtained with the existing thin PZT film as indicated by the broken lines even when the measuring voltage was $\pm 4.0 \text{ V}$, and the resistance electrical field also increased.

Figure 5 indicates the I-V curve of the thin PZT film. A relatively small value of less than 10^{-8} A/cm^2 was obtained when a positive bias was applied to the upper Au electrode. This indicates that the leakage of current of the thin film formed by the solution prepared based on this invention is substantially small while the commonly reported value is large at 10^{-6} A/cm^2 .

As schematically indicated in Figure 6(A), a broken section, as shown in Figure 6(B), is produced by forming the aforementioned upper electrode (Pt/Ti) (6) on top of a silicon substrate (1), forming a thin PZT film (7) on the top, and rupturing at the position indicated by line A-A in Figure 6(A).

Figure 7 indicates SEM (scanning electron microscope) observed pictures of the surface of the thin PZT film based on this invention at the ruptured position. It can be observed that a smooth surface is formed with fine particles uniformly spread all over. It is thought that this brings about the aforementioned excellent characteristics.

Contrary to this, the growth of the grains of PZT is relatively large at the surface of the existing thin PZT film and the smoothness of the surface is lacking, thus becoming the cause for the aforementioned deterioration in characteristics.

Next, an example will be shown in which the thin PZT film, formed using the sol gel solution based on this invention, is used in a capacitor (stack type, for example) in a dynamic RAM memory cell, for example, which is a nonvolatile memory type.

First, an example of a dynamic RAM memory cell will be indicated in Figure 16 and Figure 17.

An element region separated by a field oxide film (2) is formed at one main face of a P⁻-type silicon substrate (1), for example, and to which a transfer gate TR, that consists of a MOS transistor and a memory cell M-CEL that consists of a capacitor CAP, are formed.

5 An N⁺-type source region (3) and an N⁺ type drain region (4), for example, are respectively formed through impurity diffusion at the transfer gate TR. A word line WL is formed through a gate oxide film (5) between these regions, with a bit line BL being connected to the drain region (4) through a contact hole (11) in insulation layers (9) and (10) such as SiO₂.

10 The capacitor CAP is referred to as a stack type. A lower electrode (6) is connected to the source region (3) through a contact hole (12) in the insulating layer (10); the PZT ferroelectric film (7) and an upper electrode (8) are successively laminated on top of said lower electrode.

The ferroelectric film (7), which contains the capacitor CAP, consists of PZT, which is the Pb(Zr, Ti)O₃ film formed by the sol gel method using the aforementioned source solution based on this invention. The lower electrode (6) consists of a tungsten layer or a titanium layer, for example, with Pt deposited, for example, on top (however, the indication of Pt, for example, is eliminated in the figure). The upper electrode (8) that makes contact with the ferroelectric film consists of Pt, Au, or aluminium, for example.

Next, the manufacturing method for this memory cell M-CEL will be explained in Figures 9-16.

First, as indicated in Figure 9, a field oxide film (2) is formed on top of a P⁻-type silicon substrate (wafer) (1) by the selective oxidation process. A gate oxide film (5) and a polysilicon word line WL are respectively formed by the thermal oxidation method and the chemical gas-phase growth method. Furthermore, an N⁺-type source region (3) and a drain region (4) are respectively formed through thermal diffusion of N-type impurities such as As.

A contact hole (12) is formed by photolithography at a SiO₂ insulating layer (10) that is deposited onto the entire surface by the chemical gas-phase growth method over a source region (3).

25 As indicated in Figure 10, a lower electrode (6), having a Pt layer on top of the tungsten or titanium layer, is successively formed in a manner such that it forms a junction with the source region (3) at the contact hole (12). This can be formed by providing a certain patterning to the tungsten or titanium layer or the Pt surface layer coated onto the entire surface by photolithography.

Next, as indicated in Figure 11, a sol gel source solution (17) is coated onto the entire surface including 30 the lower electrode (6) by the spin coat method or the dip coat method. This source solution (17) has the same composition as the solution (refer to Figure 1) described above.

Next, the wafer coated with the source solution (17) is heated to a specific temperature (100-300 °C, 170 °C, for example) for 3 min, for example, the coated solution is dried, forming a dry gel film (27) as indicated in Figure 12.

35 Next, after drying is completed, the wafer is tentatively sintered at a temperature that forms the perovskite crystals (above 600 °C, 650 °C, for example) for 10 min. It is then permanently sintered (oxidation sintering) at above 600 °C (650 °C, for example) for 60 min, for example, after repeating the aforementioned drying, with a ferroelectric film (7) being formed onto the entire surface as indicated in Figure 13.

40 For forming the ferroelectric film (7) at a specific thickness (2000 Å, for example), dry film layers are laminated and the final film thickness can be obtained, without reaching the intended thickness all at once, through repeating the coating process in Figure 11, the drying process in Figure 12, and the aforementioned tentative sintering process as needed.

Next, as indicated in Figure 14, the unnecessary portion of the thin ferroelectric film (7) formed onto the entire surface is eliminated by the dry etching method, for example, and the thin PZT ferroelectric film (7) is formed in a specific pattern on top of the lower electrode (6).

Next, as indicated in Figure 15, an upper electrode (8) consisting of platinum, for example, is formed in a specific pattern at the junction with the thin ferroelectric film (7) by photolithography.

Furthermore, interlayer insulating films (10) and (9), a contact hole (11), and a bit line BL are respectively formed by publicly known methods, and a memory cell indicated in Figure 16 is prepared.

The ferroelectric film (7) of the capacitor CAP in this memory cell is formed using the source solution based on this invention. Therefore, as described above, its film surface is flat, and the electrical characteristics consisting of a large remanence value and a small leakage of current can be obtained.

55 An application example of this invention was explained above, but the aforementioned application example can be further modified based on the technical concepts of this invention.

For example, instead of lead acetate, fatty acid lead compounds such as lead 2-ethylhexanoate and lead naphthenate can be used as a starting element for preparing the aforementioned sol gel source solution.

Instead of titanium•isopropoxide, titanium alkoxides such as titaniumtetraethoxide, titaniumtetra-n-butoxide, titanium-n-butoxide, and titanium-tetra-n-pentoxide can be used.

Instead of zirconium•n-butoxide, zirconium alkoxides such as zirconium•isopropoxide, zirconium-tetraethoxide, zirconium-tetra-n-butoxide, and zirconium-tetra-n-pentoxide can be used.

5 Each of these starting elements may be used as in one type or may be a combination of several types.

The boiling temperature of each of the dilute alkoxide solutions in the aforementioned processes II and III may be established as mentioned below because the boiling point of isopropyl alcohol is 82.5°C, the boiling point of n-butanol is 98-100°C, and the boiling point of ethyl alcohol is 78.3°C.

Ti-i-propoxide: 80-190°C

10 Ti-n-butoxide: 90-190°C

Ti-tetraethoxide: 70-190°C

Zr-i-propoxide: 80-190°C

Zr-n-butoxide: 90-190°C

Zr-tetraethoxide: 70-190°C

15 Accordingly, the temperature of the thermal process in the aforementioned processes II to III, the aforementioned process I, and the aforementioned process IV can be established at 70-190°C, 120-180°C, and 120-200°C, respectively.

Instead of methoxyethanol, n-propanol, isopropanol, or n-butanol, for example, can be used as the solvent.

20 Instead of diethanolamine, alkanolamines such as dipropanolamine and triethanolamine or β -diketones such as acetylacetone, applied jointly, can be used as the stabilizer.

The composition of the ferroelectric substance that can be obtained in this invention may be varied. Also, the application is not limited only to the stack-type capacitors. A structure may be used in which the aforementioned stack-type capacitor is formed on top of a SiO₂ film and the lower electrode of said capacitor is extended and connected to the source region of the transfer gate. It can also be applied in a capacitor that is not a stack type, but has a structure in which the capacitor is integrated within a so-called trench (groove).

Results of the function of the invention

30 As described above in this invention, for forming a ferroelectric film consisting of lead zirconate titanate using the sol gel method;

a process (a) for obtaining fatty acid lead,

a process (b) for obtaining titanium•alkoxide,

35 a process (c) for obtaining zirconium•alkoxide having the same alcohol residues as said titanium•alkoxide,

and a process (d) for forming lead titanium•double alkoxide and lead zirconium•double alkoxide by mixing the aforementioned fatty acid lead, the aforementioned titanium•alkoxide, and the aforementioned zirconium•alkoxide, are respectively performed, so that the hydrolysis and condensation that follow will advance uniformly (without a substantial difference in each of the double alkoxides) because the alcohol residue for each of the aforementioned double alkoxides formed in process (d) is the same. Accordingly, the alcohol residue in the obtained high-molecular-weight compound of metallic oxides becomes uniform, the molecular structure becomes constant (without structural separation), and the types of by-products are reduced for easy elimination.

45 As a result, the intermolecular stress caused by structural separation and decomposition of the organic groups in the high polymer compound obtained can be reduced and density defects such as pores can be reduced. Thus, the thin PZT film formed from this sol gel solution has sufficient electrical characteristics such as the display of a smooth surface, a large remanence, and a small leakage of current, for example, and satisfies the demanded performance.

Claims

1. A method of forming a ferroelectric film consisting of lead zirconate titanate using the sol gel method comprising:

55 obtaining fatty acid lead

obtaining titanium•alkoxide;

obtaining zirconium•alkoxide having substantially the same alcohol residues as said titanium•alkoxide; and

forming lead titanium•double alkoxide and lead zirconium•double alkoxide by mixing the fatty acid lead, the titanium•alkoxide, and the zirconium•alkoxide.

2. The method described in Claim 1 further comprising:
 - forming a fatty acid lead [compound] with the water of crystallization eliminated by diluting a hydrate fatty acid lead with an alcohol solvent, then boiling it;
 - forming titanium•alkoxide through alcohol exchange by diluting the titanium•alkoxide used as the raw material with the alcohol solvent, then boiling it at a temperature above the boiling point of the alcohol as an element of said titanium•alkoxide;
 - forming zirconium•alkoxide through alcohol exchange by diluting zirconium•alkoxide as the raw material with the aforementioned alcohol solvent, then boiling it at a temperature above the boiling point of the alcohol as an element of said zirconium•alkoxide; and
 - forming lead titanium•double alkoxide and lead zirconium•double alkoxide by boiling the fatty acid lead, the titanium•alkoxide formed through the alcohol exchange, and the zirconium•alkoxide at a temperature above the boiling point of the fatty acid and ester as elements of the alcohol of the aforementioned alcohol solvent and the aforementioned fatty acid lead.
3. The method described in Claim 2, further comprising forming the lead titanium•double alkoxide and lead zirconium•double alkoxide, cooling the reaction products to room temperature, adjusting the concentration with the addition of an alcohol solvent, hydrolysing the reaction products through the addition of water and stirring, and polymerizing the reaction products through a condensation reaction.
4. The method of any one of Claims 1-3, further comprising adding a stabilizer consisting of an alkanolamine and/or a β -diketone wherein the amount of said addition is less than 1.0 times that of the total number of moles of metal for the constitutive metals of the ferroelectric film at least in the formation process of the lead titanium•double alkoxide and lead zirconium•double alkoxide.
5. The method described in either Claim 3 or 4, further comprising polymerising the reaction products by stirring them at a temperature above the boiling point.
6. The method of any one of Claims 3 - 5, further comprising boiling the reaction solution at a temperature above 100% after polymerization of the reaction products.
7. The method described in any of Claims 1-6, further comprising adding quaternary metallic elements such as lanthanum, niobium, and iron.
8. The method described in any of Claims 3-7, for forming a ferroelectric film by first preparing a source solution through polymerization of the reaction products, coating said source solution, forming a dry film by drying said coated source solution, and sintering said dry film.
9. A method to manufacture a capacitor by forming a ferroelectric film on top of the lower electrode through coating and drying the source solution and sintering the dry film obtained and described in Claim 8, eliminating the unnecessary portion of said film and leaving the ferroelectric film in a specific pattern on top of the aforementioned lower electrode, and further forming an upper electrode on top of said ferroelectric film.
10. The method described in Claim 9 for manufacturing a capacitor in a semiconductor memory device.
11. A method for preparing a source solution in which the source solution for the ferroelectric film is obtained through any one process described Claims 1-7.
12. The source solution prepared through any one process described in Claims 1-7.
13. A semiconductor memory device formed from the method of claim 10 or with the film formed from any of claims 1-9 or using the solution of claims 11 or 12.
